

D.

Excitable Media

Examples of Excitable Media

- Slime mold amoebas
- Cardiac tissue (& other muscle tissue)
- Cortical tissue
- Certain chemical systems (e.g., BZ reaction)
- Hodgepodge machine

Characteristics of Excitable Media

- Local spread of excitation
 - for signal propagation
- Refractory period
 - for unidirectional propagation
- Decay of signal
 - avoid saturation of medium

Behavior of Excitable Media

Stimulation

Relay (Spreading Excitation)

Continued Spreading

Recovery

Restimulation

Circular & Spiral Waves

Observed in:

- Slime mold aggregation
- Chemical systems (e.g., BZ reaction)
- Neural tissue
- Retina of the eye
- Heart muscle
- Intracellular calcium flows
- Mitochondrial activity in oocytes

Cause of Concentric Circular Waves

- Excitability is not enough
- But at certain developmental stages, cells can operate as pacemakers
- When stimulated by cAMP, they begin emitting regular pulses of cAMP

Spiral Waves

- Persistence & propagation of spiral waves explained analytically (Tyson & Murray, 1989)
- Rotate around a small core of non-excitable cells
- Propagate at higher frequency than circular
- Therefore they dominate circular in collisions
- But how do the spirals form initially?

Some Explanations of Spiral Formation

- “the origin of spiral waves remains obscure” (1997)
- Traveling wave meets obstacle and is broken
- Desynchronization of cells in their developmental path
- Random pulse behind advancing wave front

Step 0: Passing Wave Front

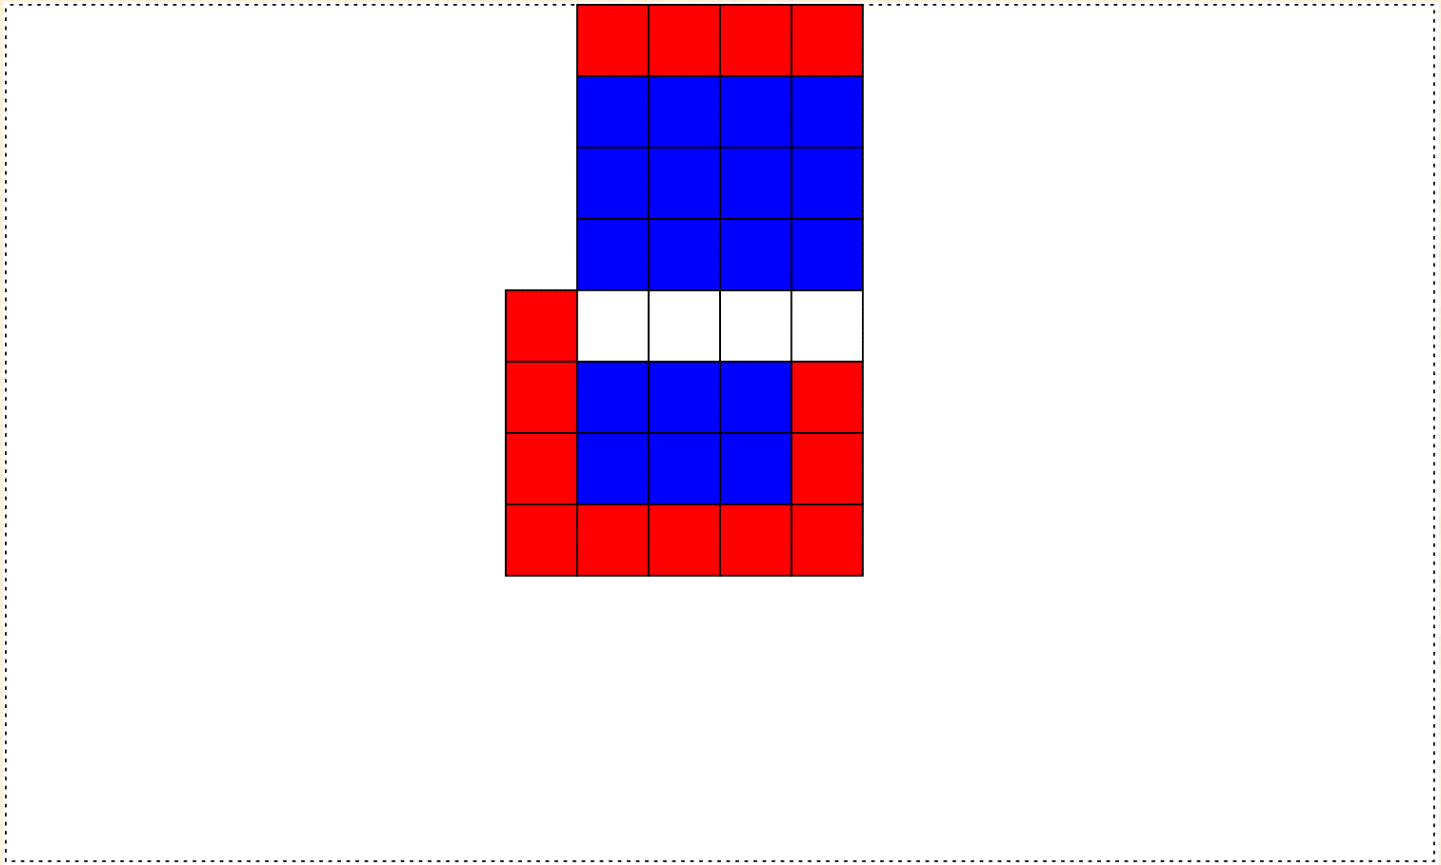

Step 1: Random Excitation

Step 2: Beginning of Spiral

Step 3

Step 4

Step 5

Step 6: Rejoining & Reinitiation

Step 7: Beginning of New Spiral

Step 8

Formation of Double Spiral

NetLogo Simulation Of Spiral Formation

- Amoebas are immobile at timescale of wave movement
- A fraction of patches are inert (grey)
- A fraction of patches has initial concentration of cAMP
- At each time step:
 - chemical diffuses
 - each patch responds to local concentration

Response of Patch

```
if patch is not refractory (brown) then  
  if local chemical > threshold then  
    set refractory period  
    produce pulse of chemical (red)  
else  
  decrement refractory period  
  degrade chemical in local area
```

Demonstration of NetLogo Simulation of Spiral Formation

[Run SlimeSpiral.nlogo](#)

Demonstration of NetLogo Simulation of Spiral Formation (a closer look)

[Run SlimeSpiralBig.nlogo](#)

Observations

- Excitable media can support circular and spiral waves
- Spiral formation can be triggered in a variety of ways
- All seem to involve inhomogeneities (broken symmetries):
 - in space
 - in time
 - in activity
- Amplification of random fluctuations
- Circles & spirals are to be expected

NetLogo Simulation of Streaming Aggregation

1. chemical diffuses
2. **if** cell is refractory (**yellow**)
3. **then** chemical degrades
4. **else** (it's excitable, colored white)
 1. **if** chemical > movement threshold **then**
take step up chemical gradient
 2. **else if** chemical > relay threshold **then**
produce more chemical (**red**)
become refractory
 3. **else** wait

Demonstration of NetLogo Simulation of Streaming

Run SlimeStream.nlogo

Typical Equations for Excitable Medium (ignoring diffusion)

- Excitation variable:

$$\dot{u} = f(u, v)$$

- Recovery variable:

$$\dot{v} = g(u, v)$$

Nullclines

Local Linearization

Fixed Points & Eigenvalues

**stable
fixed point**

real parts of
eigenvalues
are negative

**unstable
fixed point**

real parts of
eigenvalues
are positive

saddle point

one positive real &
one negative real
eigenvalue

FitzHugh-Nagumo Model

- A simplified model of action potential generation in neurons
- The neuronal membrane is an excitable medium
- B is the input bias:

$$\dot{u} = u - \frac{u^3}{3} - v + B$$

$$\dot{v} = \varepsilon(b_0 + b_1 u - v)$$

Excitable Medium
in 2D Phase Space

(EM-Phase-Plane.nlogo)

Elevated Thresholds During Recovery

Type II Model

- Soft threshold with critical regime
- Bias can destabilize fixed point

Poincaré-Bendixson Theorem

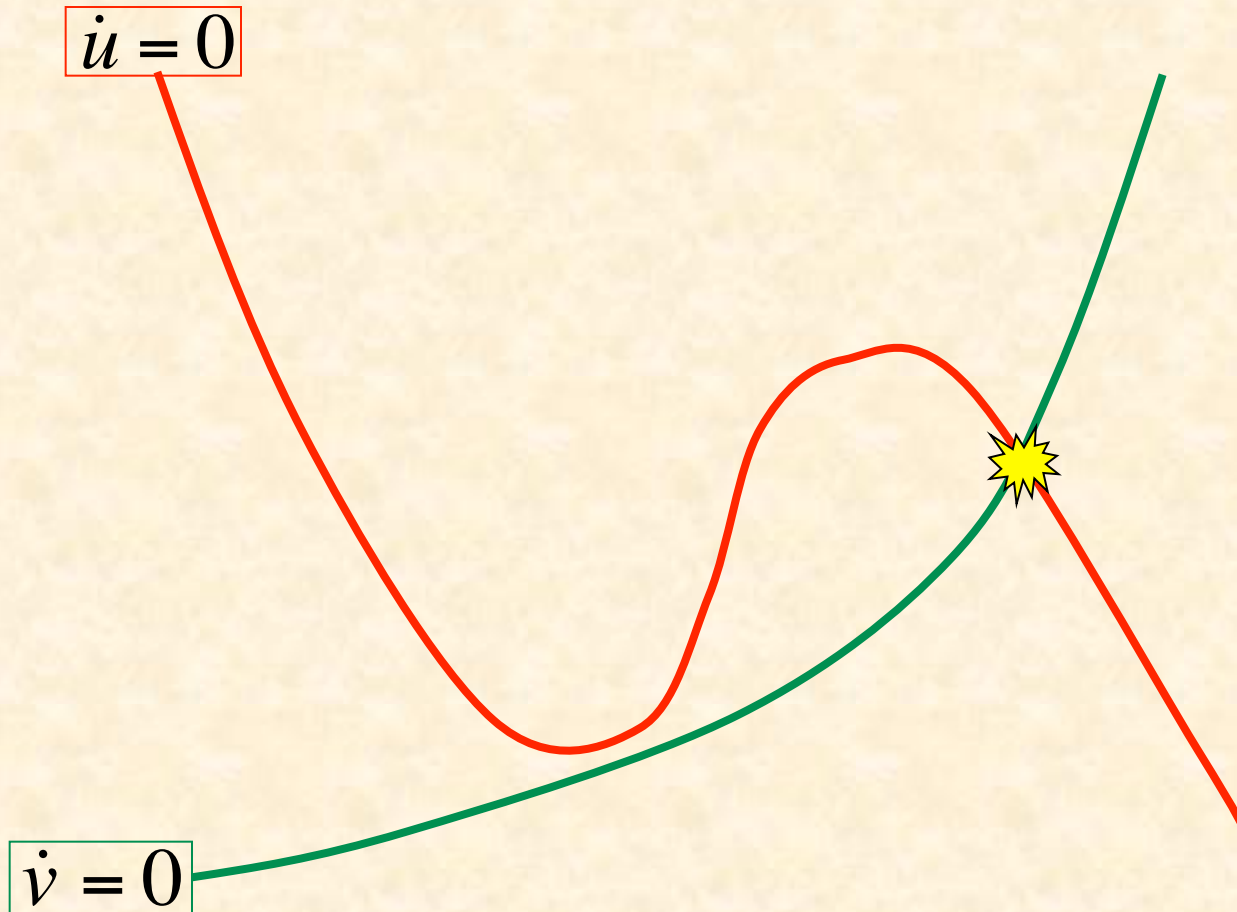

Type I Model

Type I Model (Elevated Bias)

Type I Model (Elevated Bias 2)

Type I vs. Type II

- Continuous vs. threshold behavior of frequency
- Slow-spiking vs. fast-spiking neurons

fig. < Gerstner & Kistler

Modified Martiel & Goldbeter Model for Dicty Signalling

Variables (functions of x, y, t):

β = intracellular concentration
of cAMP

γ = extracellular concentration
of cAMP

ρ = fraction of receptors in active state

Equations

$$\frac{d\beta(x,y,t)}{dt} = s\Phi(\rho,\gamma) - \beta k_i - \beta k_t \quad [1]$$

Rate of change in intracellular [cAMP] = Production of cAMP - Intracellular hydrolysis - Secretion of cAMP

$$\frac{d\gamma(x,y,t)}{dt} = \frac{k_t}{h}\beta - k_e\gamma + D\nabla^2\gamma \quad [2]$$

Rate of change in extracellular [cAMP] = Secretion of cAMP - Extracellular hydrolysis + Diffusion of cAMP

$$\frac{d\rho(x,y,t)}{dt} = f_2(\gamma)(1 - \rho) - f_1(\gamma)\rho \quad [3]$$

Rate of change in fraction of active receptor = Dephosphorylation of receptor - Phosphorylation of receptor

Positive Feedback Loop

- Extracellular cAMP increases
(γ increases)
- \Rightarrow Rate of synthesis of intracellular cAMP increases
(Φ increases)
- \Rightarrow Intracellular cAMP increases
(β increases)
- \Rightarrow Rate of secretion of cAMP increases
- (\Rightarrow Extracellular cAMP increases)

Negative Feedback Loop

- Extracellular cAMP increases
(γ increases)
- \Rightarrow cAMP receptors desensitize
(f_1 increases, f_2 decreases, ρ decreases)
- \Rightarrow Rate of synthesis of intracellular cAMP decreases
(Φ decreases)
- \Rightarrow Intracellular cAMP decreases
(β decreases)
- \Rightarrow Rate of secretion of cAMP decreases
- \Rightarrow Extracellular cAMP decreases
(γ decreases)

Dynamics of Model

- Unperturbed
⇒ cAMP concentration reaches steady state
- Small perturbation in extracellular cAMP
⇒ returns to steady state
- Perturbation $>$ threshold
⇒ large transient in cAMP,
then return to steady state
- Or oscillation (depending on model parameters)
