

VI Autonomous Agents & Self-Organization

2014/4/16

1

Autonomous Agent

- “a unit that interacts with its environment (which probably consists of other agents)
- but acts independently from all other agents in that it does not take commands from some seen or unseen leader,
- nor does an agent have some idea of a global plan that it should be following.”
—Flake (p. 261)

2014/4/16

2

A. Schools, Flocks, & Herds

“and the thousands of fishes moved as a huge beast, piercing the water. They appeared united, inexorably bound to a common fate. How comes this unity?”

— anon., 17th cent.

2014/4/16

images from EValife site

3

Coordinated Collective Movement

- Groups of animals can behave almost like a single organism
- Can execute swift maneuvers
– for predation or to avoid predation
- Individuals rarely collide, even in frenzy of attack or escape
- Shape is characteristic of species, but flexible

2014/4/16

4

Adaptive Significance

- Prey avoiding predation
- More efficient predation by predators
- Other efficiencies

2014/4/16

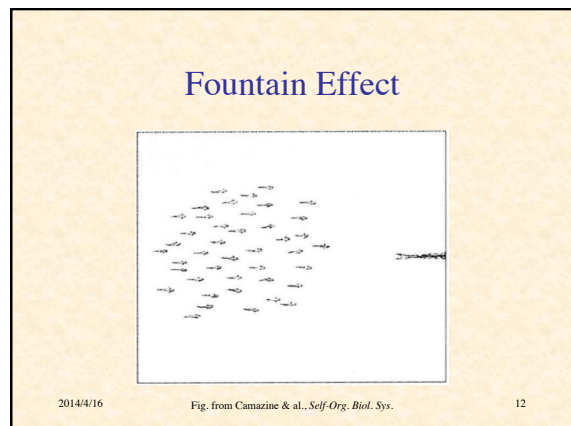

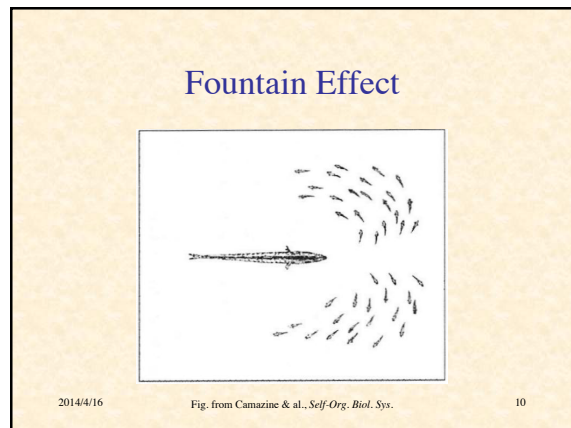

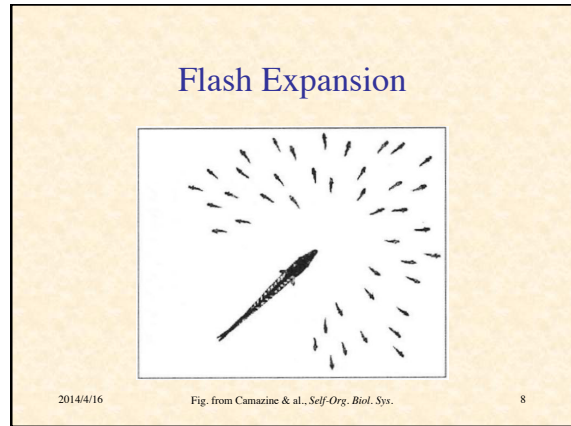

5

Avoiding Predation

- More compact aggregation
– predator risks injury by attacking
- Confusing predator by:
– united erratic maneuvers (e.g. zigzagging)
– separation into subgroups (e.g., flash expansion & fountain effect)

2014/4/16

6

Better Predation

- Coordinated movements to trap prey
 - e.g. parabolic formation of tuna
- More efficient predation
 - e.g., killer whales encircle dolphins
 - take turns eating

2014/4/16

13

Other Efficiencies

- Fish schooling may increase hydrodynamic efficiency
 - endurance may be increased up to 6x
 - school acts like “group-level vehicle”
- V-formation increases efficiency of geese
 - range 70% greater than that of individual
- Lobsters line up single file by touch
 - move 40% faster than when isolated
 - decreased hydrodynamic drag

2014/4/16

14

Characteristic Arrangement of School

- Shape is characteristic of species
- Fish have preferred distance, elevation & bearing relative to neighbors
- Fish avoid coming within a certain minimum distance
 - closer in larger schools
 - closer in faster moving schools

2014/4/16

15

Alternatives to Self-Organization

- “Templates”
 - no evidence that water currents, light, chemicals guide collective movement
- “Leaders”
 - no evidence for leaders
 - those in front may drop behind
 - those on flank may find selves in front
 - each adjusts to *several* neighbors
- “Blueprint” or “Recipe”
 - implausible for coordination of large schools
 - e.g., millions of herring, hundreds of millions of cod

2014/4/16

16

Self-Organization Hypothesis

- Simple attraction & repulsion rules generate schooling behavior
 - *positive feedback*: brings individuals together
 - *negative feedback*: but not too close
- Rules rely on local information
 - i.e. positions & headings of a few nearby fish
 - no global plan or centralized leader

2014/4/16

17

Mechanisms of Individual Coordination

- Vision
 - governs *attraction*
 - & *alignment*
- Lateral line
 - sensitive to water movement
 - provides information on speed & direction of neighbors
 - governs *repulsion*
 - & *speed matching*
- How is this information integrated into a behavioral plan?
 - most sensitive to *nearest neighbors*

2014/4/16

18

Basic Assumptions of Huth & Wissel (1992) Model

- All fish follow same rules
- Each uses some sort of weighted average of positions & orientations of nearest neighbors
- Fish respond to neighbors probabilistically
 - imperfect information gathering
 - imperfect execution of actions
- No external influences affect fish
 - e.g. no water currents, obstacles, ...

2014/4/16

19

Ranges of Behavior Patterns

2014/4/16

Fig. adapted from Camazine & al., *Self-Org. Biol. Sys.*

20

Model Behavior of Individual

1. Determine a target direction from each of three nearest neighbors:
if in *repel range*, then 180° + direction to neighbor
else if in *orient range*, then heading of neighbor
else if in *attract range*, then
 accelerate **if** ahead, decelerate **if** behind;
 return direction to neighbor
else return our own current heading
2. Determine overall target direc. as average of 3 neighbors inversely weighted by their distances
3. Turn a fraction in this direction (determined by *flexibility*) + some randomness

2014/4/16

21

Demonstration of NetLogo Simulation of Flocking/ Schooling based on Huth & Wissel Model

[Run Flock.nlogo](#)

2014/4/16

22

Limitations of Model

- Model addresses only motion in absence of external influences
- Ignores obstacle avoidance
- Ignores avoidance behaviors such as:
 - flash expansion
 - fountain effect
- Recent work (since 1997) has addressed some of these issues

2014/4/16

23

“Boids”

A model of flocks, herds, and similar cases of coordinated animal motion by Craig Reynolds (1986)

2014/4/16

24

NetLogo Simulation

- Flockmates are those within “vision”
- If nearest flockmate < minimum separation, turn away
- Else:
 - align with average heading of flockmates
 - cohere by turning toward average flockmate direction
- All turns limited to specified maxima
- Note fluid behavior from deterministic rules

2014/4/16

28

Obstacle Avoidance

- Boid flock avoiding cylindrical obstacles (Reynolds 1986)
- This model incorporates:
 - predictive obstacle avoidance
 - goal seeking (scripted path)

2014/4/16

29

Jon Klein's Flocking Algorithm

- Sight limited by “vision”
- Balances 6 “urges”:
 - be near center of flock
 - have same velocity as flockmates
 - keep spacing correct
 - avoid collisions with obstacles
 - be near center of world
 - wander throughout world
- Strength of urge affects acceleration

2014/4/16

Use in Computer Animation

- Extract from *Stanley and Stella in "Breaking the Ice"* (1987)
- store.yahoo.com/odyssey3d/comanclascli2.html

2014/4/1632

Particle Swarm Optimization

(Kennedy & Eberhart, 1995)

2014/4/1633

Motivation

- Originally a model of social information sharing
- Abstract vs. concrete spaces
 - cannot occupy same locations in concrete space
 - can in abstract space (two individuals can have same idea)
- Global optimum (& perhaps many suboptima)
- Combines:
 - private knowledge (best solution each has found)
 - public knowledge (best solution entire group has found)

2014/4/1634

Particle Swarms

Idea

- moving points in the search space, which refine their knowledge by interaction

What is a particle?

- a particle consists of:
 - \vec{x}_i position
 - \vec{v}_i velocity
 - \vec{p}_i best position found so far
 - velocity and position update rules

(Kennedy and Eberhart, 1995)

2014/4/16Fig. from EVALife site35

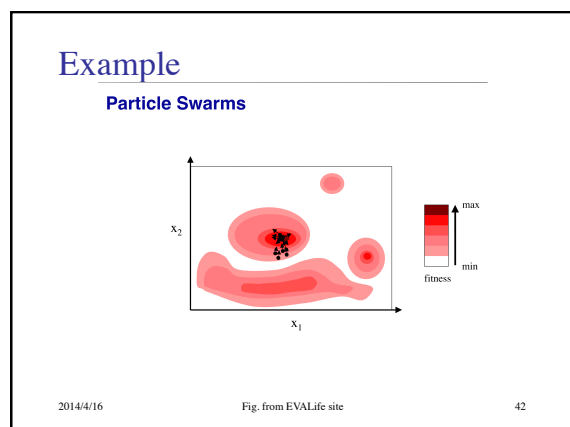

Example

Particle Swarms

(Kennedy and Eberhart, 1995)

2014/4/16Fig. from EVALife site36

Example

Particle Swarms

2014/4/16 Fig. from EValife site 43

Variables

\mathbf{x}_k = current position of particle k
 \mathbf{v}_k = current velocity of particle k
 \mathbf{p}_k = best position found by particle k
 $Q(\mathbf{x})$ = quality of position \mathbf{x}
 g = index of best position found so far
 i.e., $g = \text{argmax}_k Q(\mathbf{p}_k)$
 ϕ_1, ϕ_2 = random variables uniformly distributed over $[0, 2]$
 w = inertia < 1

2014/4/16 44

Velocity & Position Updating

$\mathbf{v}_k' = w \mathbf{v}_k + \phi_1 (\mathbf{p}_k - \mathbf{x}_k) + \phi_2 (\mathbf{p}_g - \mathbf{x}_k)$
 $w \mathbf{v}_k$ maintains direction (*inertial part*)
 $\phi_1 (\mathbf{p}_k - \mathbf{x}_k)$ turns toward private best (*cognition part*)
 $\phi_2 (\mathbf{p}_g - \mathbf{x}_k)$ turns towards public best (*social part*)

$\mathbf{x}_k' = \mathbf{x}_k + \mathbf{v}_k'$

- Allowing $\phi_1, \phi_2 > 1$ permits overshooting and better exploration (*important!*)
- Good balance of *exploration & exploitation*
- Limiting $\|\mathbf{v}_k\| < \|\mathbf{v}_{\max}\|$ controls resolution of search

2014/4/16 45

Netlogo Demonstration of Particle Swarm Optimization

[Run PSO.nlogo](#)

or [Particle Swarm Optimization.nlogo](#)

2014/4/16 46

Improvements

- Alternative velocity update equation:
 $\mathbf{v}_k' = \chi [w \mathbf{v}_k + \phi_1 (\mathbf{p}_k - \mathbf{x}_k) + \phi_2 (\mathbf{p}_g - \mathbf{x}_k)]$
 χ = constriction coefficient (controls magnitude of \mathbf{v}_k)
- Alternative neighbor relations:
 - **spatial**: limited interaction range
 - **star**: fully connected (each responds to best of all others; fast information flow)
 - **circle**: connected to K immediate neighbors (slows information flow)
 - **wheel**: connected to one axis particle (moderate information flow)

2014/4/16 47

Spatial Extension

- Spatial extension avoids premature convergence
- Preserves diversity in population
- More like flocking/schooling models

2014/4/16 Fig. from EValife site 48

Netlogo Demonstration of Particle Swarm Optimization with Collision Avoidance

[Run PSO.nlogo](#)

2014/4/16 49

Some Applications of PSO

- integer programming
- minimax problems
 - in optimal control
 - engineering design
 - discrete optimization
 - Chebyshev approximation
 - game theory
- multiobjective optimization
- hydrologic problems
- musical improvisation!

2014/4/16 50

Millonas' Five Basic Principles of Swarm Intelligence

1. *Proximity principle:*
pop. should perform simple space & time computations
2. *Quality principle:*
pop. should respond to quality factors in environment
3. *Principle of diverse response:*
pop. should not commit to overly narrow channels
4. *Principle of stability:*
pop. should not change behavior every time env. changes
5. *Principle of adaptability:*
pop. should change behavior when it's worth comp. price

2014/4/16 (Millonas 1994) 51

Kennedy & Eberhart on PSO

“This algorithm belongs ideologically to that philosophical school that allows wisdom to emerge rather than trying to impose it, that emulates nature rather than trying to control it, and that seeks to make things simpler rather than more complex. Once again nature has provided us with a technique for processing information that is at once elegant and versatile.”
