Chapter 6

SQL: SubQueries
A subquery contains one or more nested Select statements

Example: List the staff who work in the branch at ‘163 Main St’

```sql
SELECT staffNo, fName, lName, position
FROM Staff
WHERE branchNo = (SELECT branchNo
                   FROM Branch
                   WHERE street = '163 Main St');
```
If the branchNo corresponding to ‘163 Main St’ is ‘B003’, then the query resolves to:

```
SELECT staffNo, fName, lName, position
FROM Staff
WHERE branchNo = 'B003';
```
Equivalent Query with Join

Sometimes, but not always, a subquery can be replaced with a join:

```
SELECT staffNo, fName, lName, position
FROM Staff, Branch
WHERE (Staff.branchNo = Branch.branchNo)
    AND (street = '163 Main St');
```
Types of Subqueries

- **Scalar subquery**: Returns a single value
  
  **Example**: See previous example

  **Example**: List all staff whose salary is greater than the average salary, and show by how much their salary is greater than the average

  ```sql
  SELECT staffNo, fName, lName, position, salary - (SELECT AVG(salary) FROM Staff) AS salDiff
  FROM Staff
  WHERE salary > (SELECT AVG(salary) FROM Staff);
  ```
Subquery Resolution

- Suppose the average salary is 17,000.
- Then the query resolves as:
  
  ```sql
  SELECT staffNo, fName, lName, position, salary - 17000
  FROM Staff
  WHERE salary > 17000;
  ```
Using SQL Variables

- You can use SQL variables to store intermediate results
  1) Limited to storing single values (i.e., scalar values)
  2) Cannot store tables
  3) Prefix name with ‘@’

- Example

  ```sql
  SELECT @avgSalary := AVG(salary) FROM Staff;
  SELECT staffNo, fName, lName, position, salary - @avgSalary AS salDiff
  FROM Staff
  WHERE salary > @avgSalary;
  ```

- To suppress any output when you make the assignment:
  ```sql
  SELECT AVG(salary) INTO @avgSalary FROM Staff;
  ```
Types of Subqueries (Cont)

- Row subquery: Returns multiple columns possibly multiple rows
- Only used in an EXISTS predicate
- Example: Find all staff who work in a London branch office

```
SELECT staffNo, fName, lName, position
FROM Staff s
WHERE EXISTS (SELECT * FROM Branch b
              WHERE s.branchNo = b.branchNo
              AND b.city = 'London');
```
Types of Subqueries (cont)

- **Table subquery**: Returns a table suitable for use with IN (only 1 column allowed in result returned by subquery)

**Example**: List the properties that are handled by staff who work in the branch at ‘163 Main St’

```sql
SELECT propertyNo, street, city, postcode, type, rooms, rent
FROM PropertyForRent
WHERE staffNo IN (SELECT staffNo
                   FROM Staff
                   WHERE branchNo = (SELECT branchNo
                                      FROM Branch
                                      WHERE street = ‘163 Main St’));
```
SELECT propertyNo, street, city, postcode, type, rooms, rent
FROM PropertyForRent
WHERE staffNo IN (SELECT staffNo
                    FROM Staff
                    WHERE branchNo = (SELECT branchNo
                                        FROM Branch
                                        WHERE street = '163 Main St'));

SELECT * FROM PropertyForRent p NATURAL JOIN staff s
    NATURAL Join Branch b
WHERE b.street = '163 Main St';
Subquery Rules

- ORDER BY clause may not be used in a subquery
- The subquery SELECT list must consist of a single column name or expression (except row queries in EXIST predicates)
- By default, column names in a subquery refer to the table name in the FROM clause of the subquery.
  
  It is possible to refer to a table in a FROM clause of an outer query by qualifying the column name

- When a subquery is one of the two operands involved in a comparison, the subquery must be the right hand side operand

Example: In the previous aggregate subquery, it would not be permissible to have written:

```
WHERE (SELECT AVG(salary) FROM Staff) < salary;
```
Exercise

- List all guests currently staying at the Grosvenor Hotel

  Hotel   (hotelNo, hotelName, city)
  Room    (roomNo, hotelNo, type, price)
  Booking (hotelNo, guestNo, dateFrom, dateTo, roomNo)
  Guest   (guestNo, guestName, guestAddress)
Exercise

- List all guests currently staying at the Grosvenor Hotel
  
  Hotel: (hotelNo, hotelName, city)
  
  Room: (roomNo, hotelNo, type, price)
  
  Booking: (hotelNo, guestNo, dateFrom, dateTo, roomNo)
  
  Guest: (guestNo, guestName, guestAddress)

```sql
SELECT * FROM Guest
WHERE guestNo IN (SELECT guestNo FROM Booking
                   WHERE (CURRENT_DATE BETWEEN dateFrom AND
                              DATE_SUB(dateTo, INTERVAL 1 DAY)
                              AND hotelNo = (SELECT hotelNo FROM Hotel
                                              WHERE hotelName = 'Grosvenor Hotel')));
```
There is also a solution that involves join, without using a subquery

```sql
SELECT Guest.guestNo, Guest.guestName, Guest.guestAddr
FROM Guest, Booking, Hotel
WHERE (Guest.guestNo = Booking.guestNo)
  AND (CURRENT_DATE BETWEEN dateFrom AND DATE_SUB(dateTo, INTERVAL 1 DAY))
  AND (Booking.hotelNo = Hotel.hotelNo)
  AND (hotelName = 'Grosvenor Hotel');
```
