Fundamentals of Power Electronics
Objectives of Part II

Develop tools for modeling, analysis, and design of converter control systems

Need dynamic models of converters:
- How do ac variations in $v_s(t)$, $R$, or $d(t)$ affect the output voltage $v(t)$?
- What are the small-signal transfer functions of the converter?

- Extend the steady-state converter models of Chapters 2 and 3, to include CCM converter dynamics (Chapter 7)
- Construct converter small-signal transfer functions (Chapter 8)
- Design converter control systems (Chapter 9)
- Design input EMI filters that do not disrupt control system operation (Chapter 10)
- Model converters operating in DCM (Chapter 11)
- Current-programmed control of converters (Chapter 12)

Neglecting The Switching Ripple

Suppose the duty cycle is modulated sinusoidally:

\[ d(t) = D + D_m \cos \omega_m t \]

where \( D \) and \( D_m \) are constants, \(|D_m| \ll D\), and the modulation frequency \( \omega_m \) is much smaller than the converter switching frequency \( \omega_s = 2\pi f_s \).

The resulting variations in transistor gate drive signal and converter output voltage:

![Diagram showing gate drive and output voltage spectrum]

Contains frequency components at:
- Modulation frequency and its harmonics
- Switching frequency and its harmonics
- Sidebands of switching frequency

With small switching ripple, high-frequency components (switching harmonics and sidebands) are small. If ripple is neglected, then only low-frequency components (modulation frequency and harmonics) remain.

Output Voltage Spectrum
Objectives of AC Modeling

- Predict how low-frequency variations in duty cycle induce low-frequency variations in the converter voltages and currents
- Ignore the switching ripple
- Ignore complicated switching harmonics and sidebands

Approach:
- Remove switching harmonics by averaging all waveforms over one switching period

Low-frequency Averaging

Average over one switching period to remove switching ripple:

\[ L \frac{d \langle i_L(t) \rangle_{T_s}}{dt} = \langle v_L(t) \rangle_{T_s} \]
\[ C \frac{d \langle v_C(t) \rangle_{T_s}}{dt} = \langle i_C(t) \rangle_{T_s} \]

where

\[ \langle x(t) \rangle_{T_s} = \frac{1}{T_s} \int_{t}^{t+T_s} x(\tau) \, d\tau \]

Note that, in steady-state,

\[ \langle v_L(t) \rangle_{T_s} = 0 \]
\[ \langle i_C(t) \rangle_{T_s} = 0 \]

by inductor volt-second balance and capacitor charge balance.
Averaging in Steady-State

Averaging in Transient Operation
Averaging: Correct Prediction

\[ \text{Actual waveform, including ripple} \quad \text{Averaged waveform} \]

\[ \frac{v_s(t)}{L} + \frac{v(i)}{L} = \frac{d}{T_s} \left( v_s(t) \right)_{T_s} + d' \left( v(t) \right)_{T_s} \]

The net change in inductor current over one switching period is exactly equal to the period \( T_s \) multiplied by the average slope \( \left< \frac{v_L}{T_s} \right> / L \).
