

# Faraday's Law of Electromagnetic Induction

1. If the flux linking a loop (or turn) varies as a function of time, a voltage is induced between its terminals.
2. The value of the induced voltage is proportional to the rate of change of flux

$$E = -N \frac{d\phi}{dt}$$

The “-” sign indicates that the induced  $E$  has a tendency to decrease the change of flux

$$E = -2000 \times \frac{0.002 - 0.005}{0.1}$$
$$= 60 \text{ V}$$

# Voltage Induced in a Conductor

- Conclusion from Faraday's Law
  - Whenever a moving conductor (part of a coil) cuts a magnetic field  $B$ , a voltage  $\varepsilon$  is induced across its terminals, which is proportional to its active length  $l$  and relative speed  $v$ .

$$\varepsilon = -E = \frac{d\phi}{dt} = \frac{d(BA)}{dt} = \frac{BdA}{dt} = \frac{Blvdt}{dt} = Blv$$

- The direction of current  $I$  to be induced in the conductor follows the **right-hand rule**.
- We may simply use formula  $E = Blv$  to first calculate the magnitude of  $E$ ,  $B$  or  $v$  from any two of them and then judge the direction by the **right-hand rule**.

## Example 3

- $B=0.6\text{T}$ ,  $l=2\text{m}$ ,  $v=100\text{m/s}$ .

$$E = Blv = 0.6 \times 2 \times 100 = 120 \text{ V}$$

# Lorentz Force on a Conductor

- Also called electromagnetic force, it is the force a current-carrying conductor is subjected to when it is placed in a magnetic field.

$$F = BIl \quad (\text{unit: N})$$

- The direction of the Lorentz force follows the **left-hand rule**
