

# IV. Neural Network Learning

# A.

## Neural Network Learning

# Supervised Learning

- Produce desired outputs for training inputs
- Generalize reasonably & appropriately to other inputs
- Good example: pattern recognition
- Feedforward multilayer networks

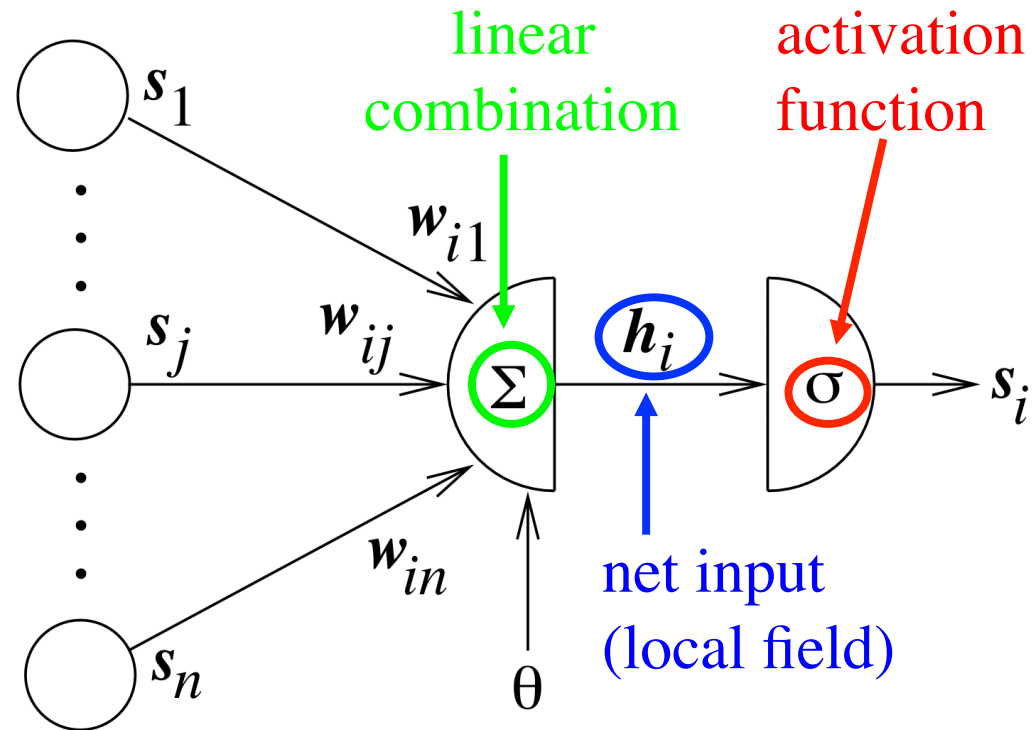

# Feedforward Network

# Typical Artificial Neuron

# Typical Artificial Neuron

# Equations

Net input:

$$h_i = \left( \sum_{j=1}^n w_{ij} s_j \right) - \theta$$

$$\mathbf{h} = \mathbf{W}\mathbf{s} - \theta$$

Neuron output:

$$s'_i = \sigma(h_i)$$

$$\mathbf{s}' = \sigma(\mathbf{h})$$

# Single-Layer Perceptron

# Variables

# Single Layer Perceptron Equations

Binary threshold activation function :

$$\sigma(h) = \Theta(h) = \begin{cases} 1, & \text{if } h > 0 \\ 0, & \text{if } h \leq 0 \end{cases}$$

$$\begin{aligned} \text{Hence, } y &= \begin{cases} 1, & \text{if } \sum_j w_j x_j > \theta \\ 0, & \text{otherwise} \end{cases} \\ &= \begin{cases} 1, & \text{if } \mathbf{w} \cdot \mathbf{x} > \theta \\ 0, & \text{if } \mathbf{w} \cdot \mathbf{x} \leq \theta \end{cases} \end{aligned}$$

# 2D Weight Vector

$$\mathbf{w} \cdot \mathbf{x} = \|\mathbf{w}\| \|\mathbf{x}\| \cos \phi$$

$$\cos \phi = \frac{v}{\|\mathbf{x}\|}$$

$$\mathbf{w} \cdot \mathbf{x} = \|\mathbf{w}\| v$$

$$\mathbf{w} \cdot \mathbf{x} > \theta$$

$$\Leftrightarrow \|\mathbf{w}\| v > \theta$$

$$\Leftrightarrow v > \frac{\theta}{\|\mathbf{w}\|}$$

# $N$ -Dimensional Weight Vector

# Goal of Perceptron Learning

- Suppose we have training patterns  $\mathbf{x}^1, \mathbf{x}^2, \dots, \mathbf{x}^P$  with corresponding desired outputs  $y^1, y^2, \dots, y^P$
- where  $\mathbf{x}^p \in \{0, 1\}^n, y^p \in \{0, 1\}$
- We want to find  $\mathbf{w}, \theta$  such that  $y^p = \Theta(\mathbf{w} \cdot \mathbf{x}^p - \theta)$  for  $p = 1, \dots, P$

# Treating Threshold as Weight

$$h = \left( \sum_{j=1}^n w_j x_j \right) - \theta$$

$$= -\theta + \sum_{j=1}^n w_j x_j$$

# Treating Threshold as Weight

$$h = \left( \sum_{j=1}^n w_j x_j \right) - \theta$$

$$= -\theta + \sum_{j=1}^n w_j x_j$$

Let  $x_0 = -1$  and  $w_0 = \theta$

$$h = w_0 x_0 + \sum_{j=1}^n w_j x_j = \sum_{j=0}^n w_j x_j = \tilde{\mathbf{w}} \cdot \tilde{\mathbf{x}}$$

# Augmented Vectors

$$\tilde{\mathbf{w}} = \begin{pmatrix} \theta \\ w_1 \\ \vdots \\ w_n \end{pmatrix} \quad \tilde{\mathbf{x}}^p = \begin{pmatrix} -1 \\ x_1^p \\ \vdots \\ x_n^p \end{pmatrix}$$

We want  $y^p = \Theta(\tilde{\mathbf{w}} \cdot \tilde{\mathbf{x}}^p)$ ,  $p = 1, \dots, P$

# Reformulation as Positive Examples

We have positive ( $y^p = 1$ ) and negative ( $y^p = 0$ ) examples

Want  $\tilde{\mathbf{w}} \cdot \tilde{\mathbf{x}}^p > 0$  for positive,  $\tilde{\mathbf{w}} \cdot \tilde{\mathbf{x}}^p \leq 0$  for negative

Let  $\mathbf{z}^p = \tilde{\mathbf{x}}^p$  for positive,  $\mathbf{z}^p = -\tilde{\mathbf{x}}^p$  for negative

Want  $\tilde{\mathbf{w}} \cdot \mathbf{z}^p \geq 0$ , for  $p = 1, \dots, P$

Hyperplane through origin with all  $\mathbf{z}^p$  on one side

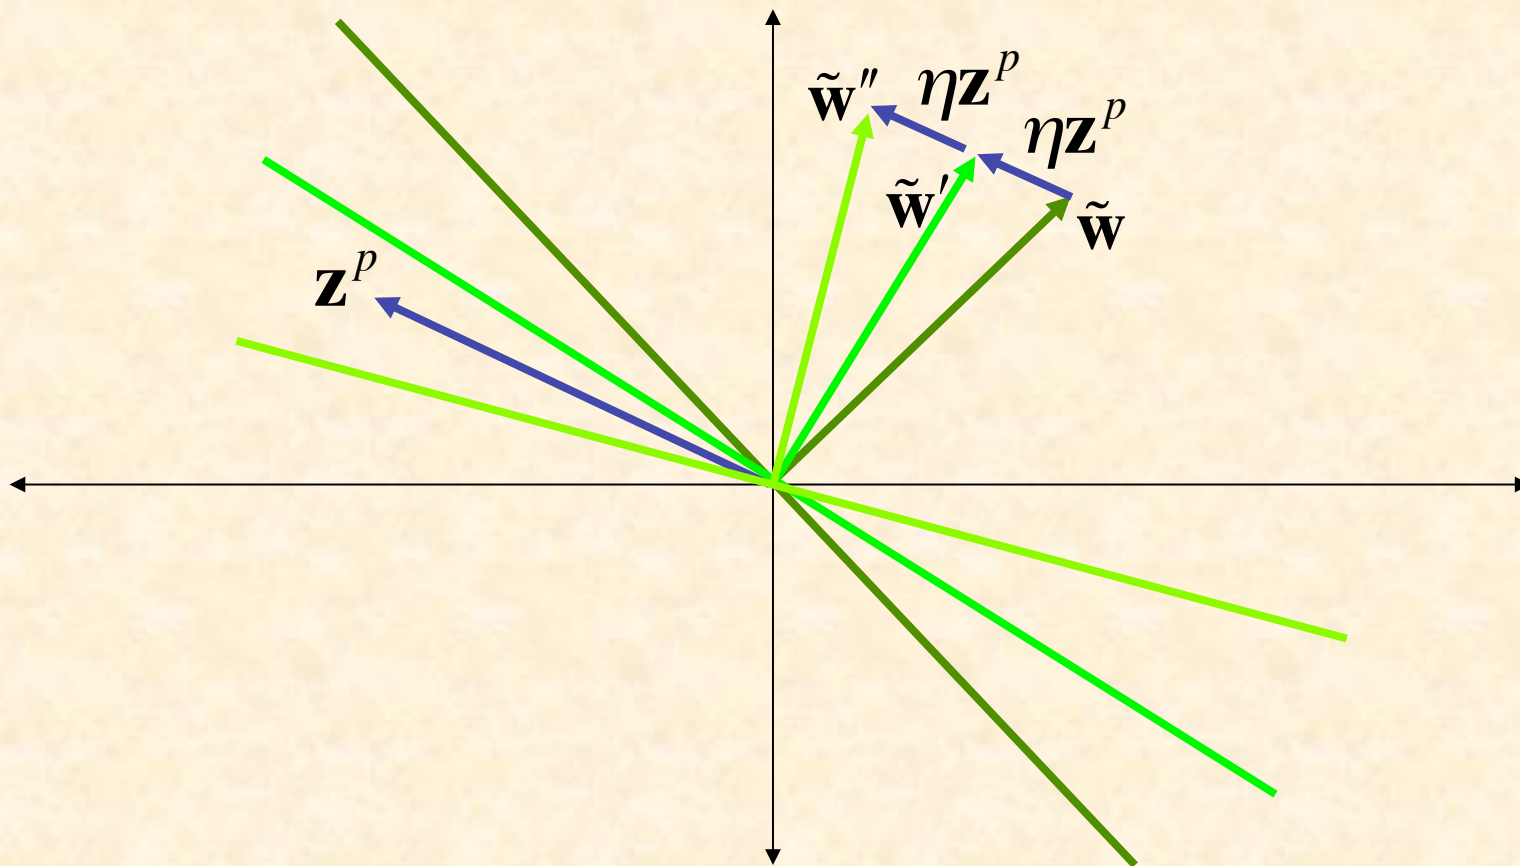

# Adjustment of Weight Vector

# Outline of Perceptron Learning Algorithm

1. initialize weight vector randomly
2. until all patterns classified correctly, do:
  - a) for  $p = 1, \dots, P$  do:
    - 1) if  $\mathbf{z}^p$  classified correctly, do nothing
    - 2) else adjust weight vector to be closer to correct classification

# Weight Adjustment

# Improvement in Performance

If  $\tilde{\mathbf{w}} \cdot \mathbf{z}^p < 0$ ,

$$\begin{aligned}\tilde{\mathbf{w}}' \cdot \mathbf{z}^p &= (\tilde{\mathbf{w}} + \eta \mathbf{z}^p) \cdot \mathbf{z}^p \\ &= \tilde{\mathbf{w}} \cdot \mathbf{z}^p + \eta \mathbf{z}^p \cdot \mathbf{z}^p \\ &= \tilde{\mathbf{w}} \cdot \mathbf{z}^p + \eta \|\mathbf{z}^p\|^2 \\ &> \tilde{\mathbf{w}} \cdot \mathbf{z}^p\end{aligned}$$

# Perceptron Learning Theorem

- If there is a set of weights that will solve the problem,
- then the PLA will eventually find it
- (for a sufficiently small learning rate)
- Note: only applies if positive & negative examples are linearly separable

# NetLogo Simulation of Perceptron Learning

[Run Perceptron-Geometry.nlogo](#)

# Classification Power of Multilayer Perceptrons

- Perceptrons can function as logic gates
- Therefore MLP can form intersections, unions, differences of linearly-separable regions
- Classes can be arbitrary *hyperpolyhedra*
- Minsky & Papert criticism of perceptrons
- No one succeeded in developing a MLP learning algorithm

# Hyperpolyhedral Classes

# Credit Assignment Problem

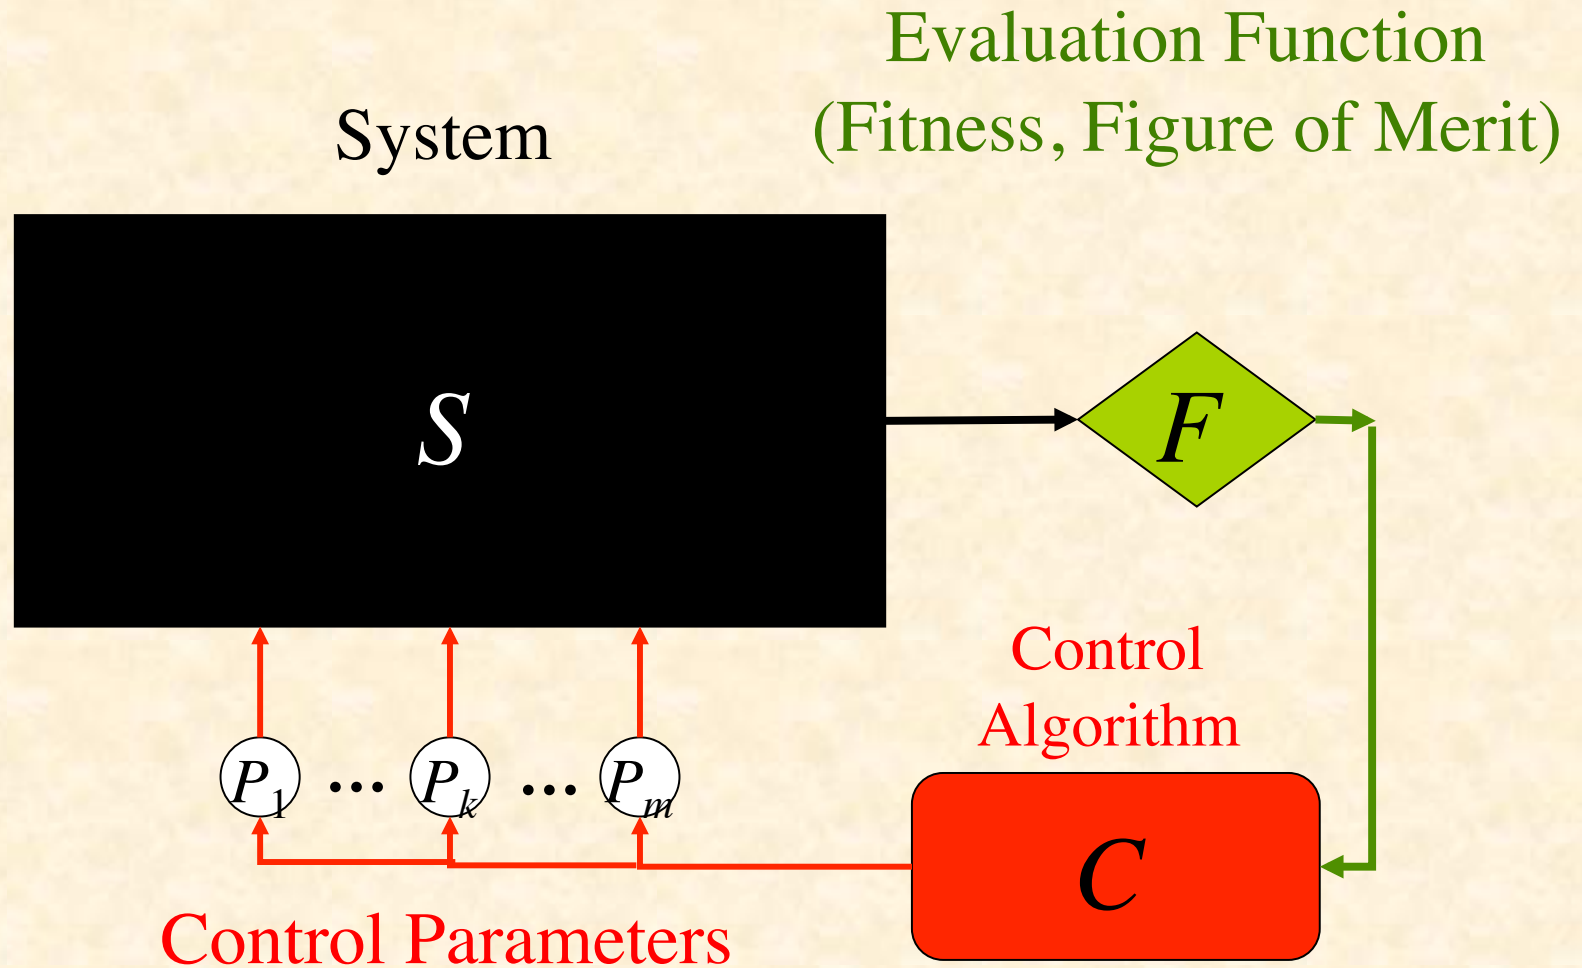

How do we adjust the weights of the hidden layers?

# NetLogo Demonstration of Back-Propagation Learning

Run Artificial Neural Net.nlogo

# Adaptive System

# Gradient

$\frac{\partial F}{\partial P_k}$  measures how  $F$  is altered by variation of  $P_k$

$$\nabla F = \begin{pmatrix} \partial F / \partial P_1 \\ \vdots \\ \partial F / \partial P_k \\ \vdots \\ \partial F / \partial P_m \end{pmatrix}$$

$\nabla F$  points in direction of maximum local increase in  $F$

# Gradient Ascent on Fitness Surface

# Gradient Ascent by Discrete Steps

# Gradient Ascent is Local But Not Shortest

# Gradient Ascent Process

$$\dot{\mathbf{P}} = \eta \nabla F(\mathbf{P})$$

Change in fitness :

$$\dot{F} = \frac{dF}{dt} = \sum_{k=1}^m \frac{\partial F}{\partial P_k} \frac{dP_k}{dt} = \sum_{k=1}^m (\nabla F)_k \dot{P}_k$$

$$\dot{F} = \nabla F \cdot \dot{\mathbf{P}}$$

$$\dot{F} = \nabla F \cdot \eta \nabla F = \eta \|\nabla F\|^2 \geq 0$$

Therefore gradient ascent increases fitness  
(until reaches 0 gradient)

# General Ascent in Fitness

Note that any adaptive process  $\mathbf{P}(t)$  will increase fitness provided :

$$0 < \dot{F} = \nabla F \cdot \dot{\mathbf{P}} = \|\nabla F\| \|\dot{\mathbf{P}}\| \cos \varphi$$

where  $\varphi$  is angle between  $\nabla F$  and  $\dot{\mathbf{P}}$

Hence we need  $\cos \varphi > 0$

or  $|\varphi| < 90^\circ$

# General Ascent on Fitness Surface

# Fitness as Minimum Error

Suppose for  $Q$  different inputs we have target outputs  $\mathbf{t}^1, \dots, \mathbf{t}^Q$

Suppose for parameters  $\mathbf{P}$  the corresponding actual outputs are  $\mathbf{y}^1, \dots, \mathbf{y}^Q$

Suppose  $D(\mathbf{t}, \mathbf{y}) \in [0, \infty)$  measures difference between target & actual outputs

Let  $E^q = D(\mathbf{t}^q, \mathbf{y}^q)$  be error on  $q$ th sample

$$\text{Let } F(\mathbf{P}) = -\sum_{q=1}^Q E^q(\mathbf{P}) = -\sum_{q=1}^Q D[\mathbf{t}^q, \mathbf{y}^q(\mathbf{P})]$$

# Gradient of Fitness

$$\nabla F = \nabla \left( -\sum_q E^q \right) = -\sum_q \nabla E^q$$

$$\begin{aligned} \frac{\partial E^q}{\partial P_k} &= \frac{\partial}{\partial P_k} D(\mathbf{t}^q, \mathbf{y}^q) = \sum_j \frac{\partial D(\mathbf{t}^q, \mathbf{y}^q)}{\partial y_j^q} \frac{\partial y_j^q}{\partial P_k} \\ &= \frac{dD(\mathbf{t}^q, \mathbf{y}^q)}{d\mathbf{y}^q} \cdot \frac{\partial \mathbf{y}^q}{\partial P_k} \\ &= \nabla_{\mathbf{y}^q} D(\mathbf{t}^q, \mathbf{y}^q) \cdot \frac{\partial \mathbf{y}^q}{\partial P_k} \end{aligned}$$

# Jacobian Matrix

Define Jacobian matrix  $\mathbf{J}^q = \begin{pmatrix} \frac{\partial y_1^q}{\partial P_1} & \cdots & \frac{\partial y_1^q}{\partial P_m} \\ \vdots & \ddots & \vdots \\ \frac{\partial y_n^q}{\partial P_1} & \cdots & \frac{\partial y_n^q}{\partial P_m} \end{pmatrix}$

Note  $\mathbf{J}^q \in \mathfrak{R}^{n \times m}$  and  $\nabla D(\mathbf{t}^q, \mathbf{y}^q) \in \mathfrak{R}^{n \times 1}$

$$\text{Since } (\nabla E^q)_k = \frac{\partial E^q}{\partial P_k} = \sum_j \frac{\partial y_j^q}{\partial P_k} \frac{\partial D(\mathbf{t}^q, \mathbf{y}^q)}{\partial y_j^q},$$

$$\therefore \nabla E^q = (\mathbf{J}^q)^T \nabla D(\mathbf{t}^q, \mathbf{y}^q)$$

# Derivative of Squared Euclidean Distance

$$\text{Suppose } D(\mathbf{t}, \mathbf{y}) = \|\mathbf{t} - \mathbf{y}\|^2 = \sum_i (t_i - y_i)^2$$

$$\begin{aligned} \frac{\partial D(\mathbf{t} - \mathbf{y})}{\partial y_j} &= \frac{\partial}{\partial y_j} \sum_i (t_i - y_i)^2 = \sum_i \frac{\partial (t_i - y_i)^2}{\partial y_j} \\ &= \frac{d(t_j - y_j)^2}{d y_j} = -2(t_j - y_j) \end{aligned}$$

$$\therefore \frac{dD(\mathbf{t}, \mathbf{y})}{d\mathbf{y}} = 2(\mathbf{y} - \mathbf{t})$$

# Gradient of Error on $q^{\text{th}}$ Input

$$\begin{aligned}\frac{\partial E^q}{\partial P_k} &= \frac{dD(\mathbf{t}^q, \mathbf{y}^q)}{d\mathbf{y}^q} \cdot \frac{\partial \mathbf{y}^q}{\partial P_k} \\ &= 2(\mathbf{y}^q - \mathbf{t}^q) \cdot \frac{\partial \mathbf{y}^q}{\partial P_k} \\ &= 2 \sum_j (y_j^q - t_j^q) \frac{\partial y_j^q}{\partial P_k}\end{aligned}$$

$$\nabla E^q = 2(\mathbf{J}^q)^T (\mathbf{y}^q - \mathbf{t}^q)$$

# Recap

$$\dot{\mathbf{P}} = \eta \sum_q (\mathbf{J}^q)^T (\mathbf{t}^q - \mathbf{y}^q)$$

To know how to decrease the differences between actual & desired outputs,

we need to know elements of Jacobian,  $\frac{\partial y_j^q}{\partial P_k}$ ,

which says how  $j$ th output varies with  $k$ th parameter (given the  $q$ th input)

The Jacobian depends on the specific form of the system, in this case, a feedforward neural network

# Multilayer Notation

# Notation

- $L$  layers of neurons labeled  $1, \dots, L$
- $N_l$  neurons in layer  $l$
- $\mathbf{s}^l =$  vector of outputs from neurons in layer  $l$
- input layer  $\mathbf{s}^1 = \mathbf{x}^q$  (the input pattern)
- output layer  $\mathbf{s}^L = \mathbf{y}^q$  (the actual output)
- $\mathbf{W}^l =$  weights between layers  $l$  and  $l+1$
- Problem: find how outputs  $y_i^q$  vary with weights  $W_{jk}^l$  ( $l = 1, \dots, L-1$ )

# Typical Neuron

# Error Back-Propagation

We will compute  $\frac{\partial E^q}{\partial W_{ij}^l}$  starting with last layer ( $l = L - 1$ )  
and working back to earlier layers ( $l = L - 2, \dots, 1$ )

# Delta Values

Convenient to break derivatives by chain rule :

$$\frac{\partial E^q}{\partial W_{ij}^{l-1}} = \frac{\partial E^q}{\partial h_i^l} \frac{\partial h_i^l}{\partial W_{ij}^{l-1}}$$

$$\text{Let } \delta_i^l = \frac{\partial E^q}{\partial h_i^l}$$

$$\text{So } \frac{\partial E^q}{\partial W_{ij}^{l-1}} = \delta_i^l \frac{\partial h_i^l}{\partial W_{ij}^{l-1}}$$

# Output-Layer Neuron

# Output-Layer Derivatives (1)

$$\begin{aligned}\delta_i^L &= \frac{\partial E^q}{\partial h_i^L} = \frac{\partial}{\partial h_i^L} \sum_k (s_k^L - t_k^q)^2 \\ &= \frac{d(s_i^L - t_i^q)^2}{dh_i^L} = 2(s_i^L - t_i^q) \frac{ds_i^L}{dh_i^L} \\ &= 2(s_i^L - t_i^q) \sigma'(h_i^L)\end{aligned}$$

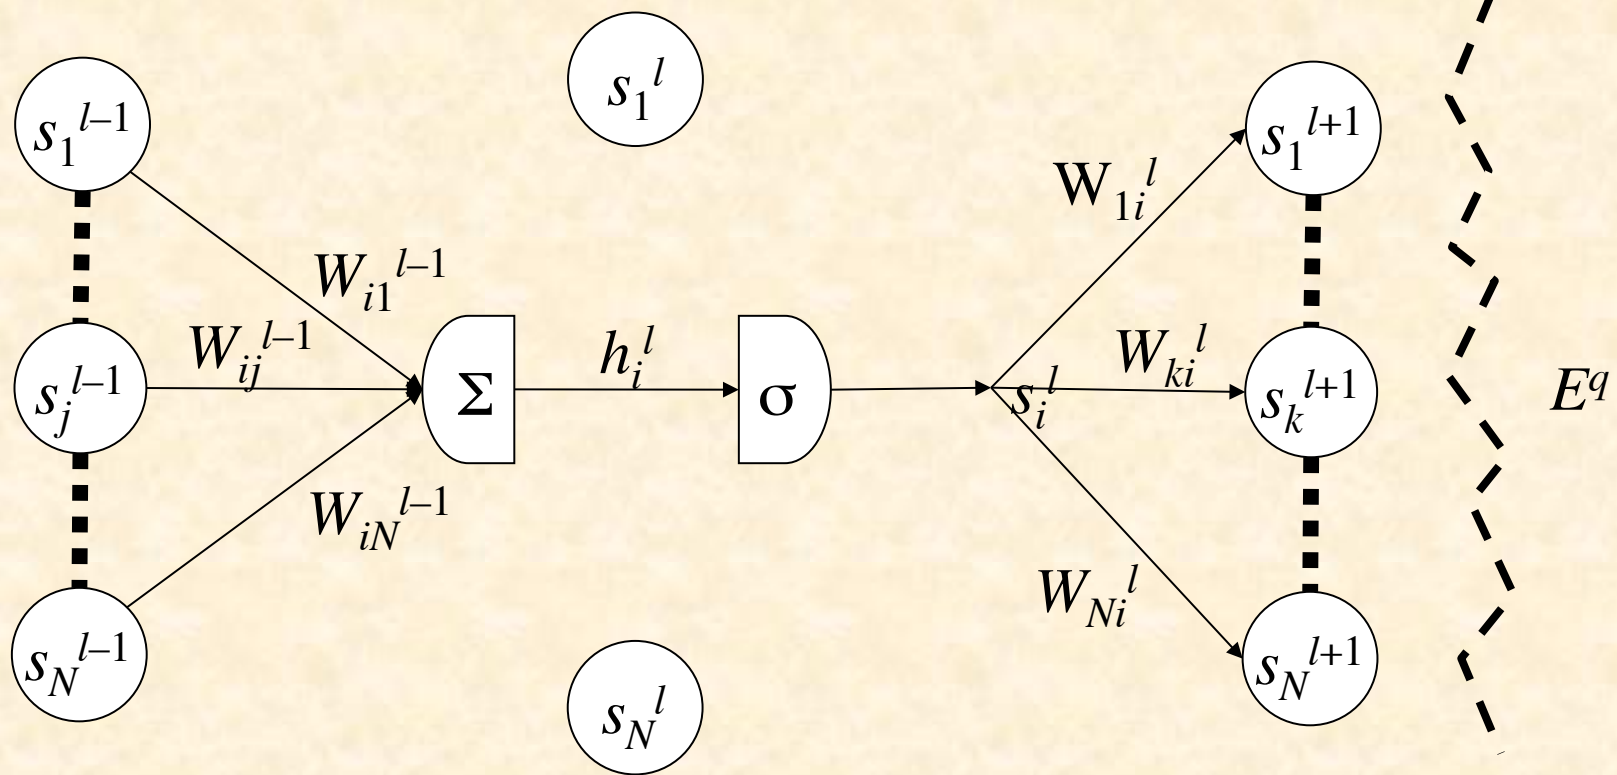

## Output-Layer Derivatives (2)

$$\frac{\partial h_i^L}{\partial W_{ij}^{L-1}} = \frac{\partial}{\partial W_{ij}^{L-1}} \sum_k W_{ik}^{L-1} s_k^{L-1} = s_j^{L-1}$$

$$\therefore \frac{\partial E^q}{\partial W_{ij}^{L-1}} = \delta_i^L s_j^{L-1}$$

$$\text{where } \delta_i^L = 2(s_i^L - t_i^q) \sigma'(h_i^L)$$

# Hidden-Layer Neuron

# Hidden-Layer Derivatives (1)

$$\text{Recall } \frac{\partial E^q}{\partial W_{ij}^{l-1}} = \delta_i^l \frac{\partial h_i^l}{\partial W_{ij}^{l-1}}$$

$$\delta_i^l = \frac{\partial E^q}{\partial h_i^l} = \sum_k \frac{\partial E^q}{\partial h_k^{l+1}} \frac{\partial h_k^{l+1}}{\partial h_i^l} = \sum_k \delta_k^{l+1} \frac{\partial h_k^{l+1}}{\partial h_i^l}$$

$$\frac{\partial h_k^{l+1}}{\partial h_i^l} = \frac{\partial \sum_m W_{km}^l s_m^l}{\partial h_i^l} = \frac{\partial W_{ki}^l s_i^l}{\partial h_i^l} = W_{ki}^l \frac{d\sigma(h_i^l)}{dh_i^l} = W_{ki}^l \sigma'(h_i^l)$$

$$\therefore \delta_i^l = \sum_k \delta_k^{l+1} W_{ki}^l \sigma'(h_i^l) = \sigma'(h_i^l) \sum_k \delta_k^{l+1} W_{ki}^l$$

## Hidden-Layer Derivatives (2)

$$\frac{\partial h_i^l}{\partial W_{ij}^{l-1}} = \frac{\partial}{\partial W_{ij}^{l-1}} \sum_k W_{ik}^{l-1} s_k^{l-1} = \frac{dW_{ij}^{l-1} s_j^{l-1}}{dW_{ij}^{l-1}} = s_j^{l-1}$$

$$\therefore \frac{\partial E^q}{\partial W_{ij}^{l-1}} = \delta_i^l s_j^{l-1}$$

$$\text{where } \delta_i^l = \sigma'(h_i^l) \sum_k \delta_k^{l+1} W_{ki}^l$$

# Derivative of Sigmoid

Suppose  $s = \sigma(h) = \frac{1}{1 + \exp(-\alpha h)}$  (logistic sigmoid)

$$\begin{aligned} D_h s &= D_h [1 + \exp(-\alpha h)]^{-1} = -[1 + \exp(-\alpha h)]^{-2} D_h (1 + e^{-\alpha h}) \\ &= -(1 + e^{-\alpha h})^{-2} (-\alpha e^{-\alpha h}) = \alpha \frac{e^{-\alpha h}}{(1 + e^{-\alpha h})^2} \\ &= \alpha \frac{1}{1 + e^{-\alpha h}} \frac{e^{-\alpha h}}{1 + e^{-\alpha h}} = \alpha s \left( \frac{1 + e^{-\alpha h}}{1 + e^{-\alpha h}} - \frac{1}{1 + e^{-\alpha h}} \right) \\ &= \alpha s(1 - s) \end{aligned}$$

# Summary of Back-Propagation Algorithm

$$\text{Output layer : } \delta_i^L = 2\alpha s_i^L (1 - s_i^L) (s_i^L - t_i^q)$$

$$\frac{\partial E^q}{\partial W_{ij}^{L-1}} = \delta_i^L s_j^{L-1}$$

$$\text{Hidden layers : } \delta_i^l = \alpha s_i^l (1 - s_i^l) \sum_k \delta_k^{l+1} W_{ki}^l$$

$$\frac{\partial E^q}{\partial W_{ij}^{l-1}} = \delta_i^l s_j^{l-1}$$

# Output-Layer Computation

# Hidden-Layer Computation

# Training Procedures

- Batch Learning
  - on each *epoch* (pass through all the training pairs),
  - weight changes for all patterns accumulated
  - weight matrices updated at end of epoch
  - accurate computation of gradient
- Online Learning
  - weight are updated after back-prop of each training pair
  - usually randomize order for each epoch
  - approximation of gradient
- Doesn't make much difference

# Summation of Error Surfaces

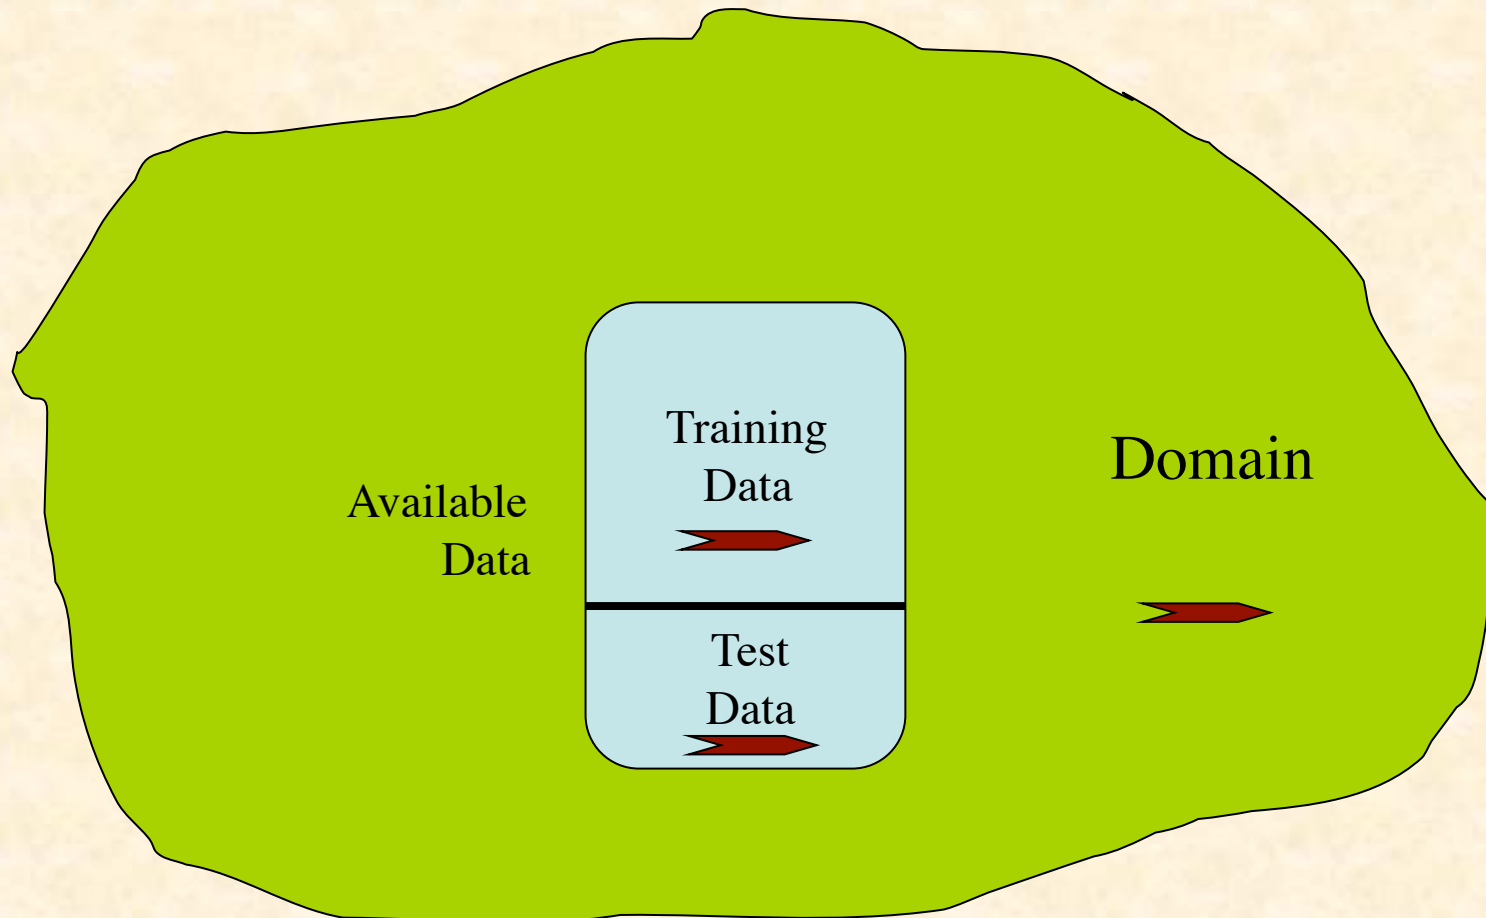

# Gradient Computation in Batch Learning

# Gradient Computation in Online Learning

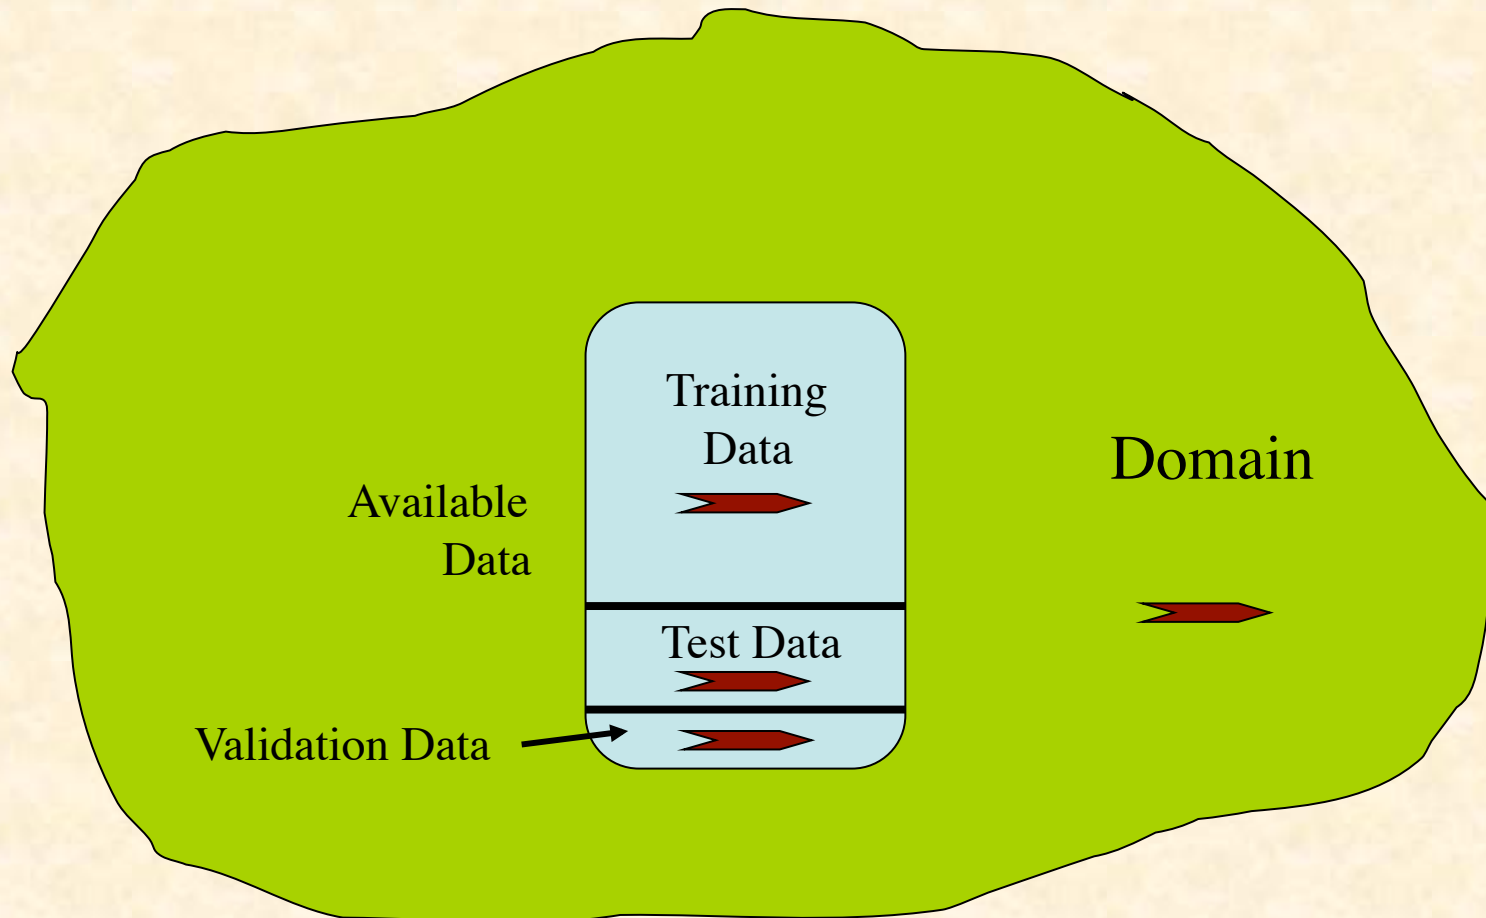

# Testing Generalization

# Problem of Rote Learning

# Improving Generalization

# A Few Random Tips

- Too few neurons and the ANN may not be able to decrease the error enough
- Too many neurons can lead to rote learning
- Preprocess data to:
  - standardize
  - eliminate irrelevant information
  - capture invariances
  - keep relevant information
- If stuck in local min., restart with different random weights

# Run Example BP Learning

# Beyond Back-Propagation

- Adaptive Learning Rate
- Adaptive Architecture
  - Add/delete hidden neurons
  - Add/delete hidden layers
- Radial Basis Function Networks
- Recurrent BP
- Etc., etc., etc....

# What is the Power of Artificial Neural Networks?

- With respect to Turing machines?
- As function approximators?

# Can ANNs Exceed the “Turing Limit”?

- There are many results, which depend sensitively on assumptions; for example:
- Finite NNs with real-valued weights have super-Turing power (Siegelmann & Sontag ‘94)
- Recurrent nets with Gaussian noise have sub-Turing power (Maass & Sontag ‘99)
- Finite recurrent nets with real weights can recognize all languages, and thus are super-Turing (Siegelmann ‘99)
- Stochastic nets with rational weights have super-Turing power (but only P/POLY, BPP/log<sup>\*</sup>) (Siegelmann ‘99)
- But computing classes of functions is not a very relevant way to evaluate the capabilities of neural computation

# A Universal Approximation Theorem

Suppose  $f$  is a continuous function on  $[0,1]^n$

Suppose  $\sigma$  is a nonconstant, bounded,  
monotone increasing real function on  $\mathfrak{R}$ .

For any  $\varepsilon > 0$ , there is an  $m$  such that

$\exists \mathbf{a} \in \mathfrak{R}^m$ ,  $\mathbf{b} \in \mathfrak{R}^n$ ,  $\mathbf{W} \in \mathfrak{R}^{m \times n}$  such that if

$$F(x_1, \dots, x_n) = \sum_{i=1}^m a_i \sigma \left( \sum_{j=1}^n W_{ij} x_j + b_j \right)$$

$$[\text{i.e., } F(\mathbf{x}) = \mathbf{a} \cdot \sigma(\mathbf{W}\mathbf{x} + \mathbf{b})]$$

then  $|F(\mathbf{x}) - f(\mathbf{x})| < \varepsilon$  for all  $\mathbf{x} \in [0,1]^n$

# One Hidden Layer is Sufficient

- Conclusion: One hidden layer is sufficient to approximate any continuous function arbitrarily closely

# The Golden Rule of Neural Nets

Neural Networks are the  
*second-best* way  
to do *everything!*
