

Adaptive Significance

- Selects most profitable from array of food sources
- Selects shortest route to it
 longer paths abandoned within 1–2 hours
- Adjusts amount of exploration to quality of identified sources
- Collective decision making can be as accurate and effective as some vertebrate individuals

4

6

4/23/17

Observations on Trail Formation

- Two equal-length paths presented at same time: ants choose one at random
- Sometimes the longer path is initially chosen
- Ants may remain "trapped" on longer path, once established
- Or on path to lower quality source, if it's discovered first
- But there may be advantages to sticking to paths - easier to follow
 - easier to protect trail & source

- safer

4/23/17

Process of Trail Formation

- 1. Trail laying
- 2. Trail following

Trail Laying

- On discovering food, forager lays chemical trail while returning to nest
- only ants who have found food deposit pheromoneOthers stimulated to leave nest by:
 - the trail

4/23/17

- the recruitor exciting nestmates (sometimes)
- In addition to defining trail, pheromone:
 - serves as general orientation signal for ants outside nest
 serves as arousal signal for ants inside

7

Additional Complexities

- Some ants begin marking on return from discovering food
- Others on their first return trip to food
- Others not at all, or variable behavior
- Probability of trail laying decreases with number of trips

4/23/17

Frequency of Trail Marking

- Ants modulate frequency of trail marking
- May reflect quality of source – hence more exploration if source is poor
- May reflect orientation to nest
 - ants keep track of general direction to nest
 - and of general direction to food source
 - trail laying is less intense if the angle to homeward direction is large

Probability of Choosing One of Two Branches

- Let $C_{\rm L}$ and $C_{\rm R}$ be units of pheromone deposited on left & right branches
- Let $P_{\rm L}$ and $P_{\rm R}$ be probabilities of choosing them
- Then:

$$P_{\rm L} = \frac{(C_{\rm L} + 6)^2}{(C_{\rm L} + 6)^2 + (C_{\rm R} + 6)^2}$$

11

12

• Nonlinearity amplifies probability

Additional Adaptations

- If a source is crowded, ants may return to nest or explore for other sources
- New food sources are preferred if they are near to existing sources
- Foraging trails may rotate systematically around a nest

Pheromone Evaporation

- Trails can persist from several hours to several months
- Pheromone has mean lifetime of 30-60 min.
- But remains detectable for many times this
- Long persistence of pheromone prevents switching to shorter trail
- Artificial ant colony systems rely more heavily on evaporation

13

15

4/23/17

Environment

- Nest emits nest-scent, which
 - diffuses uniformly
 - decays slowly
 - provides general orientation signal
 - by diffusing around barriers, shows possible paths around barriers
- Trail pheromone
 - emitted by ants carrying food
 - diffuses uniformly
 - decays quickly
- Food detected only by contact

	Resnick Ant Behavior	
1.	Looking for food:	
	else move toward increasing concentration	
2.	Acquiring food:	
	if at food then pick it up, turn around, & begin depositing pheromone	
3.	Returning to nest:	
	deposit pheromone & decrease amount available	
	move toward increasing nest-scent	
4.	Depositing food:	
	if at nest then	
	deposit food, stop depositing pheromone, & turn around	
5.	Repeat forever	
4/23/	17	16

- To reinforce portions of good solutions that contribute to their goodness
- To reinforce good solutions directly

4/23/17

• Accomplished by pheromone accumulation

20

- To avoid premature convergence (*stagnation*)
- Accomplished by *pheromone evaporation*

23

24

Cooperation

- For simultaneous exploration of different solutions
- Accomplished by:
 - multiple ants exploring solution space
 - *pheromone trail* reflecting multiple perspectives on solution space

4/23/17

Traveling Salesman Problem

- Given the travel distances between N cities – may be symmetric or not
- Find the shortest route visiting each city exactly once and returning to the starting point
- NP-hard
- Typical combinatorial optimization problem

25

26

27

4/23/17

Ant System for Traveling Salesman Problem (AS-TSP)

- During each iteration, each ant completes a tour
- During each tour, each ant maintains *tabu list* of cities already visited
- Each ant has access to
 - distance of current city to other cities
 - intensity of local pheromone trail
- Probability of next city depends on both
- 4/23/17

4/23/17

Transition Rule

- Let $\eta_{ij} = 1/d_{ij} =$ "nearness" of city *j* to current city *i*
- Let τ_{ij} = strength of trail from *i* to *j*
- Let J_i^k = list of cities ant k still has to visit after city i in current tour
- Then transition probability for ant k going from i to $j \in J_i^k$ in tour t is:

 $p_{ij}^{k} = \frac{\left[\boldsymbol{\tau}_{ij}(t)\right]^{\alpha} \left[\boldsymbol{\eta}_{ij}\right]^{\beta}}{\sum_{l \in J_{i}^{k}} \left[\boldsymbol{\tau}_{il}(t)\right]^{\alpha} \left[\boldsymbol{\eta}_{il}\right]^{\beta}}$

Pheromone Deposition

• Let $T^k(t)$ be tour t of ant k

4/23/17

- Let $L^k(t)$ be the length of this tour
- After completion of a tour, each ant *k* contributes:

$$\Delta \tau_{ij}^{k} = \begin{cases} Q \\ L^{k}(t) \\ 0 & \text{if } (i,j) \notin T^{k}(t) \end{cases}$$

28

29

30

Pheromone Decay
Define total pheromone deposition for tour *t*:
$$\Delta \tau_{ij}(t) = \sum_{k=1}^{m} \Delta \tau_{ij}^{k}(t)$$

• Let ρ be decay coefficient

• Define trail intensity for next round of tours:

$$\tau_{ij}(t+1) = (1-\rho)\tau_{ij}(t) + \Delta\tau_{ij}(t)$$

Number of Ants is Critical

• Too many:

4/23/17

- suboptimal trails quickly reinforced
- ∴ early convergence to suboptimal solution
- Too few:

- don't get cooperation before pheromone decays
- Good tradeoff: number of ants = number of cities (*m* = *n*)

Improvement: "Elitist" Ants

- Add a few $(e \approx 5)$ "elitist" ants to population
- Let T^+ be best tour so far
- Let L^+ be its length
- Each "elitist" ant reinforces edges in T^+ by Q/L^+
- Add e more "elitist" ants
- This applies accelerating positive feedback to best tour

31

Improving Network Routing

- 1. Nodes periodically send *forward ants* to some recently recorded destinations
- 2. Collect information on way
- 3. Die if reach already visited node
- 4. When reaches destination, estimates time and turns into *backward ant*
- 5. Returns by same route, updating routing tables

35

36

4/23/17

Some Applications of ACO

- Routing in telephone networks
- Vehicle routing
- Job-shop scheduling
- Constructing evolutionary trees from nucleotide sequences
- Various classic NP-hard problems
 - shortest common supersequence, graph coloring, quadratic assignment, ...

Improvements as Optimizer

- Can be improved in many ways
- E.g., combine local search with ant-based methods
- As method of stochastic combinatorial optimization, performance is promising, comparable with best heuristic methods
- Much ongoing research in ACO
- But optimization is not a principal topic of this course

37

The Nonconvergence Issue

- AS often does not converge to single solution
- Population maintains high diversity
- A bug or a feature?
- Potential advantages of nonconvergence:

 avoids getting trapped in local optima
 promising for dynamic applications
- Flexibility & robustness are more important than optimality in natural computation

40

41

42

4/23/17

Natural Computation

Natural computation is computation that occurs in nature or is inspired by computation occurring in nature

Optimization in Natural Computation

- Good, but suboptimal solutions may be preferable to optima if:
 - suboptima can be obtained more quickly
 - suboptima can be adapted more quickly
 - suboptima are more robust
 - an ill-defined suboptimum may be better than a sharp optimum
- "The best is the enemy of the good" (Le mieux est l'ennemi du bien. – Voltaire)
